Network Analysis:

The Hidden Structures behind the Webs We Weave 17-213 / 17-668

Power and Centrality in Social Networks Thursday, September 21, 2023

Patrick Park & Bogdan Vasilescu

Carnegie Mellon University School of Computer Science

2-min Quiz, on Canvas

"Central" actors are powerful

Relational view of the individual

So far, we covered dyads and triads as basic building blocks of networks

The relational view has been the overarching theme

- relations between two people?
- relations among three people?

The same relational view applies to the many ways to study the individual

This relational approach sharply contrasts with widely used approaches

- Surveys ask individuals about their attributes, beliefs, and actions
- Majority of statistical models assume that individuals are like disconnected atoms
 - Independent, identically distributed variables assumption (IID).

Which node is the most "prominent"?

In contrast, network analysis focuses on the relation and the interdependence among individuals

- **Opinions** are influenced by network neighbors
- Individual's **status** and importance comes from their position in the network
- Individuals can leverage their position to influence opinions, selectively spread or block information, and control opportunities
- **Power** that an individual can wield is fundamentally relational

A network position of power and prominence is a "central" position

- Power and prominence are multifaceted
- Therefore, there can be many ways to measure "centrality"

So many ways to define "centrality"

Centrality

Degree

degree_centrality (G) Compute the degree centrality for nodes. in degree centrality (G) Compute the in-degree centrality for nodes. out_degree_centrality (G) Compute the out-degree centrality for nodes.

Eigenvector

<pre>eigenvector_centrality (G[, max_iter, tol,])</pre>	Compute the eigenvector centrality for the graph G.
<pre>eigenvector_centrality_numpy (G[, weight,])</pre>	Compute the eigenvector centrality for the graph G.
katz_centrality (G[, alpha, beta, max_iter,])	Compute the Katz centrality for the nodes of the graph G.
katz_centrality_numpy (G[, alpha, beta,])	Compute the Katz centrality for the graph G.

Current Flow Betweenness

	<pre>current_flow_betweenness_centrality (G[,])</pre>	Compute current-flow betweenness centrality for nodes.
	<pre>edge_current_flow_betweenness_centrality (G)</pre>	Compute current-flow betweenness centrality for edges.
	approximate_current_flow_betweenness_centrality (G)	Compute the approximate current-flow betweenness centrality for nodes.
	<pre>current_flow_betweenness_centrality_subset (G,)</pre>	Compute current-flow betweenness centrality for subsets of nodes.
e	<pre>dge_current_flow_betweenness_centrality_subset (G,)</pre>	Compute current-flow betweenness centrality for edg using subsets of nodes.

Closeness

<pre>closeness_centrality (G[, u, distance,])</pre>	Compute closeness centrality for nodes.
<pre>incremental_closeness_centrality (G, edge[,])</pre>	Incremental closeness centrality for nodes.

Current Flow Closeness

<pre>current_flow_closeness_centrality (G[,])</pre>	Compute current-flow closeness centrality nodes.			
information controlity (GI weight durpe 1)	Compute current-flow closeness centrality for			
internation_centratity (o[, weight, dtype,])	nodes.			

(Shortest Path) Betweenness

<pre>betweenness_centrality (G[, k, normalized,])</pre>	Compute the shortest-path betweenness centrality for nodes. Compute betweenness centrality for a subset of nodes.				
<pre>betweenness_centrality_subset (G, sources,)</pre>					
<pre>edge_betweenness_centrality (G[, k,])</pre>	Compute betweenness centrality for edges.				
<pre>edge_betweenness_centrality_subset (G, [,])</pre>	Compute betweenness centrality for edges for a subset of nodes.				

Communicability Betweenness

Returns subgraph communicability for all pairs communicability_betweenness_centrality (G) of nodes in G.

ity for Group Centrality

g	<pre>proup_betweenness_centrality (G, C[,])</pre>	Compute the group betweenness centrality for group of nodes.
gr	<pre>roup_closeness_centrality (G, S[, weight])</pre>	Compute the group closeness centrality for a group of nodes.
	<pre>group_degree_centrality (G, S)</pre>	Compute the group degree centrality for a grou of nodes.
	<pre>group_in_degree_centrality (G, S)</pre>	Compute the group in-degree centrality for a group of nodes.
	<pre>group_out_degree_centrality (G, S)</pre>	Compute the group out-degree centrality for a group of nodes.
	<pre>prominent_group (G, k[, weight, C,])</pre>	Find the prominent group of size k in graph G

Load

load centrality (GI, v, cutoff, normalized, ...]) Compute load centrality for nodes. edge_load_centrality (G[, cutoff]) Compute edge load.

Subgraph

subgraph centrality (G) Returns subgraph centrality for each node in G. subgraph_centrality_exp (G) Returns the subgraph centrality for each node of G. estrada index (G) Returns the Estrada index of a the graph G.

Harmonic Centrality

harmonic_centrality (G[, nbunch, distance, ...]) Compute harmonic centrality for nodes.

Dispersion

edges

dispersion (G[, u, v, normalized, alpha, b, c]) Calculate dispersion between u and v in G.

Reaching

<pre>local_reaching_centrality (G, v[, paths,])</pre>	Returns the local reaching centrality of a node in a directed graph.				
global_reaching_centrality (G[, weight,])	Returns the global reaching centrality of a				
	directed graph.				

Percolation

percolation_centrality (G[, attribute, ...]) Compute the percolation centrality for nodes.

Second Order Centrality

second_order_centrality (G) Compute the second order centrality for nodes of G.

Trophic

trophic_levels (G[, weight])

trophic differences (G[, weight])

trophic_incoherence_parameter (G[, weigh

VoteRank

Select voterank (G[, number of nodes])

Laplacian

laplacian centrality (G[, normalized, ...])

...

So many ways to define "centrality"

We will cover the four most widely used centrality measures in network analysis

- Degree centrality
- Closeness centrality
- Betweenness centrality
- Eigenvector centrality

Insight: Central nodes have many connections

The number of ties of a node, **normalized by network** size (*g*-1).

$$C_D(i) = \frac{k_i}{g-1}$$

Normalization allows for comparison across different networks

One of the most basic and fundamental quantities in network science

Having many connections means highly visible and in an advantageous position to exchange a broad range of information

Degree centrality was, by far, the most popular measure up to the early 2000s

However, its prominence arguably diminished in the past two decades **Why?**

However, its prominence arguably diminished in the past two decades Why?

2001 - 2019 -Case-Insensitive Smoothing of 2 -2001-2019 English (2019) -0.0000110% 0.0000100% betweenness centrality 0.0000090% 0.0000080% dearee centrality 0.0000070% 0.0000050% 0.0000040% closeness centrali envector cent 0.0000030% 0.0000020% 0.00000109 0.000000% 2004 2016 2018

In large-scale networks (post-2000s), degree centrality becomes a "local" measure

Closeness Centrality

Insight: The position that minimizes the distance to all other positions is the most central

Centroid of the U.S.

Closeness Centrality

Insight: The position that minimizes the distance to all other positions is the most central

Telephone game

Application:

- Systems where traversing the network is costly
- A system where information attrition rate is high
- \rightarrow The node closest to all other nodes can obtain more accurate messages
- \rightarrow A source of power

Closeness Centrality

Central nodes have short paths to other nodes

Calculated as the reciprocal of the sum of pairwise distances

$$C_c(i) = [\sum_{j=1}^g d(i,j)]^{-1}$$

Normalized by size of network

 $C_c(i) = (g-1) [\sum_{j=1}^g d(i,j)]^{-1}$

A global measure that uses information from the entire network

Node is central if it sits on many shortest paths

Nodes positioned in Information bottleneck are central

Those nodes have more control over the distribution of information and other resources

Number of shortest paths node is on

Node *i*'s betweenness is the sum of the probabilities that *i* is on the shortest paths of all node pairs in the network

$$C_B(i) = \sum_{j < k} PL(i, j, k) / PL(j, k)$$

 $PL(i,j,k) \rightarrow$ Number of shortest paths involving i

 $PL(j,k) \rightarrow$ Number of shortest paths between j and k

$$C_B(i) = \sum_{j < k} PL(i, j, k) / PL(j, k)$$

Maximum probability PL(i,j,k) = PL(j,k) = 1 is when *i* sits on every shortest path between *j* and *k*.

Then, the theoretical maximum C(i) is when *i* sits on every shortest path for every pair of nodes (excluding *i*)

Q: What is the number of node pairs (dyads) excluding *i* in a graph with *g* nodes?

$$C_B(i) = \sum_{j < k} PL(i, j, k) / PL(j, k)$$

Maximum probability PL(i,j,k) = PL(j,k) = 1 is when *i* sits on every shortest path between *j* and *k*.

Then, the theoretical maximum C(i) is when *i* sits on every shortest path for every pair of nodes (excluding *i*)

 \rightarrow Normalize by the total number of node pairs excluding $i \rightarrow (g-1)(g-2)/2$

$$C_B'(i) = \frac{C_B(i)}{\left[\frac{(g-1)(g-2)}{2}\right]}$$

Who is more central?

 \rightarrow Someone who knows five (well connected) celebrities vs. someone who knows five ordinary people

Eigenvector centrality quantifies this insight

 \rightarrow One's Eigenvector centrality is determined by the neighbors' eigenvector centrality, which in turn are determined by their neighbors' eigenvector centrality ...

Who is more central?

 \rightarrow Someone who knows five (well connected) celebrities vs. someone who knows five ordinary people

Eigenvector centrality quantifies this intuition

 \rightarrow One's Eigenvector centrality is determined by the neighbors' eigenvector centrality, which in turn are determined by their neighbors' eigenvector centrality ...

Red node has two (purple) friends who are themselves highly connected

 \rightarrow Highest Eigenvector centrality

Pink nodes have lower degree centrality than the blue nodes, but they are connected to the red node

Given an adjacency matrix **A**, eigenvector centrality of node *i* is:

- *i*'s weighted degree where each of *i*'s edge is weighted by the degree of the neighbor, *j*

$$\lambda C_E(i) = \sum_j A_{ij} C_E(j)$$

Given adjacency matrix **A**, compute the eigenvector **x** corresponding to the principal eigenvalue λ^* of **A**

Each element in **x** is the eigenvector centrality value of the corresponding node

$$\lambda x_{1} = (x_{2} + x_{3} + x_{4})$$

$$\lambda x_{2} = x_{1}$$

$$\lambda x_{3} = x_{1}$$

$$\lambda x_{4} = x_{1}$$

$$\begin{bmatrix} x_{1} \\ x_{2} \\ x_{3} \\ x_{4} \end{bmatrix} = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_{1} \\ x_{2} \\ x_{3} \\ x_{4} \end{bmatrix}$$

λ

$$\lambda \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} \longrightarrow \lambda \mathbf{x} = \mathbf{A} \mathbf{x}$$

Characteristic equation for matrix A is:

$$\lambda^4 - 3\lambda^2 = \lambda^2(\lambda^2 - 3) = 0$$

Eigenvalues are $-\sqrt{3}$, 0, 0, $\sqrt{3}$ Principal eigenvalue $\lambda^* = \sqrt{3}$

$$\lambda \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} \longrightarrow \lambda \mathbf{x} = \mathbf{A} \mathbf{x}$$

Find the principal eigenvector for $\lambda^* = \sqrt{3}$

Ax-λx=0 (**A**-√3**I**)x=0

x=[√3, 1, 1, 1]

v1 has highest eigenvector centrality, $\sqrt{3}$

v2, v3, v4 = 1

Google's original PageRank algorithm ranks web pages using a variant of eigenvector centrality

- A node's PageRank is a function of the PageRank of its in-neighbors
- Normalize the eigenvector centrality of the in-neighbor nodes with their outdegree

Google's original PageRank algorithm ranks web pages using a variant of eigenvector centrality

- A node's PageRank is a function of the PageRank of its in-link neighbors
- Normalize the eigenvector centrality of the in-link neighbors with their outdegrees
 - Why?

Similarities among Centrality Measures

Average correlations between centrality measures (N=58).

Pearson correlation

Valente et al. 2008

Similarities among Centrality Measures

Sometimes, the relationship is non-linear \rightarrow lower linear correlation (Pearson)

- Example: Closeness centrality and the log of degree centrality are highly correlated (redundant)
- If such a strong relationship, why do we care about computationally expensive closeness centrality?

Closeness centrality (inverse)

Evans and Chen 2022

Similar, but also different

Different centrality measures capture different intuitions

In a graph, the node with highest degree is not necessarily the node with the highest betweenness or closeness

Summary

Centrality as a general term for measuring a node's position of "prominence" in the network

Degree: sheer connections

Closeness: shortest path distance

Betweenness: node's presence in shortest paths

Eigenvector: degree weighted by the degree of the neighbors

These measures are highly correlated, but conceptually distinct
